## Overview

- Discretized effective actions
- Introduction
- Gaussian halving
- Euler's summation formula
- Recursive approach: many-body systems
- Diagonalization of the evolution operator
- Discretization approach
- Space-discretization errors
- Evolution-time errors
- Energy eigenvalues and eigenstates
- Application to BECs
- Calculation of global properties
- Density profiles
- Time-of-flight graphs
- Concluding remarks
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Formulation of the path integral formalism (1)

- Amplitudes for transition from an initial state $|\alpha\rangle$ to a final state $|\beta\rangle$ in time $T$ can be written as

$$
A(\alpha, \beta ; T)=\langle\beta| e^{-\frac{i}{\hbar} \hat{H} T}|\alpha\rangle
$$

- For technical reasons, usually we use imaginary time
- The standard derivation starts from the identity

$$
A(\alpha, \beta ; T)=\int d q_{1} \cdots d q_{N-1} A\left(\alpha, q_{1} ; \epsilon\right) \cdots A\left(q_{N-1}, \beta ; \epsilon\right)
$$

dividing the evolution into $N$ steps of the length $\epsilon=T / N$.This expression is exact.

- Next step is approximate calculation of short-time amplitudes up to the first order in $\epsilon$, and we get $(\hbar=1)$

$$
A_{N}(\alpha, \beta ; T)=\frac{1}{(2 \pi \epsilon)^{N / 2}} \int d q_{1} \cdots d q_{N-1} e^{-S_{N}}
$$

A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

ScIENTIFIC CロMPபTING LABロRATロRY

Introduction

## Illustration of the discretization of trajectories

## Formulation of the path integral formalism (2)

- Continual amplitude $A(\alpha, \beta ; T)$ is obtained in the limit $N \rightarrow \infty$ of the discretized amplitude $A_{N}(\alpha, \beta ; T)$,

$$
A(\alpha, \beta ; T)=\lim _{N \rightarrow \infty} A_{N}(\alpha, \beta ; T)
$$

- Discretized amplitude $A_{N}$ is expressed as a multiple integral of the function $e^{-S_{N}}$, where $S_{N}$ is called discretized action
- For a theory defined by the Lagrangian $L=\frac{1}{2} \dot{q}^{2}+V(q)$, (naive) discretized action is given by

$$
S_{N}=\sum_{n=0}^{N-1}\left(\frac{\delta_{n}^{2}}{2 \epsilon}+\epsilon V\left(\bar{q}_{n}\right)\right)
$$

where $\delta_{n}=q_{n+1}-q_{n}, \bar{q}_{n}=\frac{q_{n+1}+q_{n}}{2}$.
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Numerical approach to the calculation of path integrals (1)

- Path integral formalism is ideally suited for numerical approach, with physical quantities defined by discretized expressions as multiple integrals of the form

$$
\int d q_{1} \cdots d q_{N-1} e^{-S_{N}}
$$

- Monte Carlo (MC) is the method of choice for calculation of such intergals
- However, although multiple integrals can be calculated very accurately and efficiently by MC, there still remains the difficult $N \rightarrow \infty$ limit
- This is what makes the outlined constructive definition of path integrals difficult to use in practical applications

## Numerical approach to the calculation of path integrals (2)

- Discretization used in the definition of path integrals is not unique; in fact, the choice of the discretization is of essential importance
- Naive discretized action (in the mid-point prescription) gives discretized amplitudes converging to the continuum as slow as $1 / N$
- Using special tricks we can get better convergence (e.g. left prescription gives $1 / N^{2}$ convergence when partition function is calculated)
- However, this cannot be done in a systematic way, nor it can be used in all cases (e.g. left prescription cannot be used for systems with ordering ambiguities)
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

ScIENTIFIC CロMPபTINE LABロRATロRY

Effective actions
Diagonalization Application to BECs Concluding remarks

Introduction

## Typical $1 / N$ convergence of naively discretized path integrals

## Discretized effective actions (1)

- Discretized actions can be classified according to the speed of convergence of discretized path integrals to continuum values
- It is possible to introduce different discretized actions which contain some additional terms compared to the naive discretized action
- These additional terms must vanish in the $N \rightarrow \infty$ limit, and should not change continuum values of amplitudes, e.g.

$$
\sum_{n=0}^{N-1} \epsilon^{3} V^{\prime}\left(\bar{q}_{n}\right) \rightarrow \epsilon^{2} \int_{0}^{T} d t V^{\prime}(q(t)) \rightarrow 0
$$

- Additional terms in discretized actions are chosen so that they speed up the convergence of path integrals
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Discretized effective actions (2)

- Improved discretized actions have been earlier constructed through several approaches, including
- generalizations of the Trotter-Suzuki formula
- improvements in the short-time propagation
- expansion of the propagator by the number of derivatives
- This improved the convergence of general path integrals for partition functions from $1 / N$ to $1 / N^{4}$
- Li-Broughton effective potential

$$
V^{L B}=V+\frac{1}{24} \epsilon^{2} V^{\prime 2}
$$

in the left prescription gives $1 / N^{4}$ convergence

- Derivation of the above expression makes use of the cyclic property of the trace - the improvement is valid for partition functions only

## Improving effective actions

- We present an approach enabling a substantial speedup in the convergence of path integrals through studying the relation between different discretizations
- Using this approach we have derived the integral equation connecting discretized effective actions of different coarseness, which allows their systematic derivation. This leads to improved $1 / N^{p}$ convergence of path integrals for one-particle systems in $d=1$ - Gaussian halving
- We also present the generalization to many-body systems, based on solving the recursive relations for discretized effective action, derived from equations for short-time amplitudes - recursive approach
- The presented results are highly related to recently developed systematic approach by Chin and collaborators
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Ideal discretization (1)

- Ideal discretized action $S^{*}$ is defined as the action giving exact continual amplitudes $A_{N}=A$ for any discretization $N$
- For the free particle, the naive discretized action is ideal
- From the completeness relation

$$
A(\alpha, \beta ; T)=\int d q_{1} \cdots d q_{N-1} A\left(\alpha, q_{1} ; \epsilon\right) \cdots A\left(q_{N-1}, \beta ; \epsilon\right)
$$

it follows that the ideal discretized action $S_{n}^{*}$ for the propagation time $\epsilon$ is given by

$$
A\left(q_{n}, q_{n+1} ; \epsilon\right)=(2 \pi \epsilon)^{-\frac{1}{2}} e^{-S_{n}^{*}}
$$

- Ideal discretized action $S^{*}$ is the sum of terms $S_{n}^{*}$

## Ideal discretization（2）

－In general case，the ideal discretized action can be written as

$$
S_{n}^{*}=\frac{\delta_{n}^{2}}{2 \epsilon}+\epsilon W_{n}
$$

where $W$ is the effective potential which contains $V\left(\bar{q}_{n}\right)$ and corrections
－From the definition of the ideal discretized action it follows

$$
W_{n}=W\left(\delta_{n}, \bar{q}_{n} ; \epsilon\right)
$$

－From the reality of imaginary－time amplitudes，i．e．from the hermiticity of real－time amplitudes we obtain

$$
W\left(\delta_{n}, \bar{q}_{n} ; \epsilon\right)=W\left(-\delta_{n}, \bar{q}_{n} ; \epsilon\right)
$$

ScIENTIFIC CロMPபTINE LABロRATロRY

Effective actions
Diagonalization Application to BECs Concluding remarks

Introduction

## Relation between different discretizations（2）

A．Balaž：Properties of Quantum Systems via Num．Diagonalization of the Evolution Operator

## Relation between different discretizations (3)

- If we integrate out all odd-numbered coordinates, for a given discretized 2 N -action we get the effective N -action

$$
e^{-\widetilde{S}_{N}}=\left(\frac{2}{\pi \epsilon_{N}}\right)^{\frac{N}{2}} \int d x_{1} \cdots d x_{N} e^{-S_{2 N}}
$$

- However, if we use the ideal discretized action, then we get

$$
e^{-S_{N}^{*}}=\left(\frac{2}{\pi \epsilon_{N}}\right)^{\frac{N}{2}} \int d x_{1} \cdots d x_{N} e^{-S_{2 N}^{*}}
$$

## Integral equation for the effective action

- From previous relation we obtain integral equation for the effective potential in the form

$$
\begin{aligned}
e^{-\epsilon_{N} W\left(\delta_{n}, \bar{q}_{n} ; \epsilon_{N}\right)}=\left(\frac{2}{\pi \epsilon_{N}}\right)^{\frac{1}{2}} & \int_{-\infty}^{+\infty} d y e^{-\frac{2}{\epsilon_{N}} y^{2}} \times \\
& G\left(\bar{q}_{n}+y ; q_{n}, q_{n+1}, \frac{\epsilon_{N}}{2}\right)
\end{aligned}
$$

where function $G$ is defined as

$$
\begin{aligned}
& -\frac{2}{\epsilon_{N}} \ln G\left(x ; q_{n}, q_{n+1}, \epsilon_{N}\right)= \\
& \quad W\left(q_{n+1}-x, \frac{q_{n+1}+x}{2} ; \epsilon_{N}\right)+W\left(x-q_{n}, \frac{x+q_{n}}{2} ; \epsilon_{N}\right)
\end{aligned}
$$

## Euler's summation formula (1)

- For ordinary integrals Euler's summation formula reads

$$
\begin{aligned}
& I[f]=\int_{0}^{T} f(t) d t=\sum_{n=1}^{N} f\left(t_{n}\right) \epsilon_{N}-\frac{\epsilon_{N}}{2} \sum_{n=1}^{N} f^{\prime}\left(t_{n}\right) \epsilon_{N}+ \\
& \quad \frac{\epsilon_{N}^{2}}{6} \sum_{n=1}^{N} f^{\prime \prime}\left(t_{n}\right) \epsilon_{N}+\ldots
\end{aligned}
$$

- $I[f]$ is now written as a series in time step $\epsilon_{N}$,

$$
I[f]=I_{N}\left[f^{(p)}\right]+O\left(\epsilon_{N}^{p}\right)
$$

where $f^{(p)}$ is the corresponding initial part of the ideal $f^{*}$

- Using $W$, we will derive Euler's summation formula for path integrals

## Euler's summation formula (2)

- When we expand function $G$ in a series in the first argument around $\bar{q}_{n}$, we get the following equation for $W$

$$
W\left(\delta_{n}, \bar{q}_{n} ; \epsilon_{N}\right)=-\frac{1}{\epsilon_{N}} \ln \left[\sum_{k=0}^{\infty} \frac{G^{(2 k)}\left(\bar{q}_{n} ; q_{n}, q_{n+1}, \frac{\epsilon_{N}}{2}\right)}{(2 k)!!}\left(\frac{\epsilon_{N}}{4}\right)^{k}\right]
$$

- Further application of asymptotic expansion makes use of the expansion of the ideal effective potential in a series

$$
W\left(\delta_{n}, \bar{q}_{n} ; \epsilon_{N}\right)=\sum_{k=0}^{\infty} \delta_{n}^{2 k} g_{k}\left(\bar{q}_{n} ; \epsilon_{N}\right)
$$

- From the equation for $W$ we get a system of differential equations for functions $g_{k}$
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Euler's summation formula (3)

- If we expand functions $g_{k}$ into series in the time step $\epsilon$

$$
g_{k}\left(\bar{q}_{n} ; \epsilon_{N}\right)=\sum_{m=0}^{p-k-1} \epsilon_{N}^{m} g_{k m}\left(\bar{q}_{n}\right) \quad(k=0, \ldots, p-1)
$$

we obtain a system of equations that is easily decoupled and can be solved in functions $g_{k}$

- Note that in the above expression the sum is limited according to the consistency condition which follows from the diffusion relation $\delta^{2} \propto \epsilon$
- Boundary condition for the above system is $g_{00}=V$, obtained from limits $\delta_{n}^{2} \rightarrow 0$ and $\epsilon_{N} \rightarrow 0$, in which $W$ reduces to

$$
W\left(0, \bar{q}_{n} ; 0\right)=V\left(\bar{q}_{n}\right)
$$

A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Euler's summation formula (4)

- To level $p=3$ we get

$$
\begin{aligned}
& g_{0}\left(\bar{q}_{n} ; \epsilon_{N}\right)=V\left(\bar{q}_{n}\right)+\epsilon_{N} \frac{V^{\prime \prime}\left(\bar{q}_{n}\right)}{12}+\epsilon_{N}^{2}\left[-\frac{V^{\prime}\left(\bar{q}_{n}\right)^{2}}{24}+\frac{V^{(4)}\left(\bar{q}_{n}\right)}{240}\right] \\
& g_{1}\left(\bar{q}_{n} ; \epsilon_{N}\right)=\frac{V^{\prime \prime}\left(\bar{q}_{n}\right)}{24}+\epsilon_{N} \frac{V^{(4)}\left(\bar{q}_{n}\right)}{480} \\
& g_{2}\left(\bar{q}_{n} ; \epsilon_{N}\right)=\frac{V^{(4)}\left(\bar{q}_{n}\right)}{1920}
\end{aligned}
$$

- Ideal effective action on the convergence level $p$ is given as

$$
S_{N}^{(p)}=\sum_{n=0}^{N-1}\left[\frac{\delta_{n}^{2}}{2 \epsilon_{N}}+\epsilon_{N} \sum_{k=0}^{p-1} \delta_{n}^{2 k} g_{k}\left(\bar{q}_{n} ; \epsilon_{N}\right)\right]
$$

- This ensures the improved convergence

$$
A_{N}^{(p)}(\alpha, \beta ; T)=A(\alpha, \beta ; T)+O\left(\epsilon_{N}^{p}\right)
$$

A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Recursive approach

- Gaussian halving is developed and applicable for one-particle one-dimensional systems only
- For many-body systems in arbitrary dimensions we have developed two equivalent approaches
- First is based on direct calculation of $\epsilon$-expansion of short-time amplitudes, expressed as expectation values of the corresponding free theory
- following the original idea from the book by H. Kleinert
- Here we present second approach, based on solving recursive relations for the discretized action, derived from Schrödinger's equation for amplitudes.
- This approach is by far the most efficient, both for many-body and one-body systems.
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Effective actions for many-body systems

- We start from Schrödinger's equation for the amplitude $A\left(q, q^{\prime} ; \epsilon\right)$ for a system of $M$ non-relativistic particles in $d$ spatial dimensions

$$
\begin{aligned}
& {\left[\frac{\partial}{\partial \epsilon}-\frac{1}{2} \sum_{i=1}^{M} \triangle_{i}+V(q)\right] A\left(q, q^{\prime} ; \epsilon\right)=0} \\
& {\left[\frac{\partial}{\partial \epsilon}-\frac{1}{2} \sum_{i=1}^{M} \triangle_{i}^{\prime}+V\left(q^{\prime}\right)\right] A\left(q, q^{\prime} ; \epsilon\right)=0}
\end{aligned}
$$

- Here $\triangle_{i}$ and $\triangle_{i}^{\prime}$ are $d$-dimensional Laplacians over initial and final coordinates of the particle $i$, while $q$ and $q^{\prime}$ are $d \times M$ dimensional vectors representing positions of all particles at the initial and final time.
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Equation for the ideal effective potential

- If we express short-time amplitude $A\left(q, q^{\prime} ; \epsilon\right)$ by the ideal discretized effective potential $W$

$$
A\left(q, q^{\prime} ; \epsilon\right)=\frac{1}{(2 \pi \epsilon)^{d M / 2}} \exp \left[-\frac{\delta^{2}}{2 \epsilon}-\epsilon W\right]
$$

we obtain equation for the effective potential in terms of $x=\delta / 2, \bar{x}=\left(q+q^{\prime}\right) / 2, V_{ \pm}=V(\bar{x} \pm x)$

$$
\begin{aligned}
W+x \cdot \partial W+\epsilon \frac{\partial W}{\partial \epsilon}-\frac{1}{8} \epsilon \bar{\partial}^{2} W & -\frac{1}{8} \epsilon \partial^{2} W+\frac{1}{8} \epsilon^{2}(\bar{\partial} W)^{2}+ \\
& +\frac{1}{8} \epsilon^{2}(\partial W)^{2}=\frac{V_{+}+V_{-}}{2}
\end{aligned}
$$

ScIENTIFIC CロMPபTINE LABロRATロRY

## Recursive relations（1）

－As before，the effective potential is given as a series

$$
W(x, \bar{x} ; \epsilon)=\sum_{m=0}^{\infty} \sum_{k=0}^{m} W_{m, k}(x, \bar{x}) \epsilon^{m-k}
$$

where

$$
W_{m, k}(x, \bar{x})=x_{i_{1}} x_{i_{2}} \cdots x_{i_{2 k}} c_{m, k}^{i_{1}, \ldots, i_{2 k}}(\bar{x})
$$

－Coefficients $W_{m, k}$ are obtained from recursive relations

$$
\begin{aligned}
8(m+k+1) & W_{m, k}=\bar{\partial}^{2} W_{m-1, k}+\partial^{2} W_{m, k+1}- \\
& -\sum_{l=0}^{m-2} \sum_{r}\left(\bar{\partial} W_{l, r}\right) \cdot\left(\bar{\partial} W_{m-l-2, k-r}\right)- \\
& -\sum_{l=1}^{m-2} \sum_{r}\left(\partial W_{l, r}\right) \cdot\left(\partial W_{m-l-1, k-r+1}\right)
\end{aligned}
$$

A．Balaž：Properties of Quantum Systems via Num．Diagonalization of the Evolution Operator

## Recursive relations (2)

- Diagonal coefficients are easily obtained from recursive relations

$$
W_{m, m}=\frac{1}{(2 m+1)!}(x \cdot \bar{\partial})^{2 m} V
$$

- Off-diagonal coefficients are obtained by applying recursive relations in the following order

A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Effective actions for many－body systems

－To level $p=3$ ，effective action is given by

$$
\begin{aligned}
W_{0,0} & =V \\
W_{1,1} & =\frac{1}{6}(x \cdot \bar{\partial})^{2} V \\
W_{1,0} & =\frac{1}{12} \bar{\partial}^{2} V \\
W_{2,2} & =\frac{1}{120}(x \cdot \bar{\partial})^{4} V \\
W_{2,1} & =\frac{1}{120}(x \cdot \bar{\partial})^{2} \bar{\partial}^{2} V \\
W_{2,0} & =\frac{1}{240} \bar{\partial}^{4} V-\frac{1}{24}(\bar{\partial} V) \cdot(\bar{\partial} V)
\end{aligned}
$$

ScIENTIFIC CロMPபTINE LABロRATロRY

## Effective discretized $p=4$ action

$$
\begin{aligned}
S_{N}^{(p=4)} & =\sum\left\{\epsilon\left(\frac{1}{2} \frac{\delta_{i} \delta_{i}}{\epsilon^{2}}+V\right)\right. \\
& +\frac{\epsilon^{2}}{12} \partial_{k, k}^{2} V+\frac{\epsilon \delta_{i} \delta_{j}}{24} \partial_{i, j}^{2} V \\
& -\frac{\epsilon^{3}}{24} \partial_{i} V \partial_{i} V+\frac{\epsilon^{3}}{240} \partial_{i, i, j, j}^{4} V+\frac{\epsilon^{2} \delta_{i} \delta_{j}}{480} \partial_{i, j, k, k}^{4} V+\frac{\epsilon \delta_{i} \delta_{j} \delta_{k} \delta_{l}}{1920} \partial_{i, j, k, l}^{4} V \\
& +\frac{\epsilon^{4}}{6720} \partial_{i, i, j, j, k, k}^{6} V-\frac{\epsilon^{4}}{120} \partial_{i} V \partial_{i, k, k}^{3} V-\frac{\epsilon^{4}}{360} \partial_{i, j}^{2} V \partial_{i, j}^{2} V \\
& -\frac{\epsilon^{3} \delta_{i} \delta_{j}}{480} \partial_{k} V \partial_{k, i, j}^{3} V+\frac{\epsilon^{3} \delta_{i} \delta_{j}}{13440} \partial_{i, j, k, k, l, l}^{6} V-\frac{\epsilon^{3} \delta_{i} \delta_{j}}{1440} \partial_{i, k}^{2} V \partial_{k, j}^{2} V \\
& \left.+\frac{\epsilon^{2} \delta_{i} \delta_{j} \delta_{k} \delta_{l}}{53760} \partial_{i, j, k, l, m, m}^{6} V+\frac{\epsilon \delta_{i} \delta_{j} \delta_{k} \delta_{l} \delta_{m} \delta_{n}}{322560} \partial_{i, j, k, l, m, n}^{6} V\right\}
\end{aligned}
$$

## Diagrammatic form of effective actions (1)

- Derived recursive relations can be represented in a diagrammatic form if we introduce

$$
\begin{gathered}
\delta_{i j}=i \longrightarrow j, \quad x_{i}=\quad \times i \\
\bar{\partial}_{i_{1}} \bar{\partial}_{i_{2}} \ldots \bar{\partial}_{i_{l}} V=W_{i_{1}} \bigcup_{i_{2}}, \quad W_{i_{l}}=\underbrace{m, k}_{\underbrace{* \cdots}_{2 k} \times} .
\end{gathered}
$$

- Diagrammatic form of diagonal coefficients

$$
W_{m, m}=\underbrace{\underbrace{*}}_{\underbrace{\times \cdots}_{2 m}}=\frac{1}{(2 m+1)!}+\underbrace{\underbrace{*}_{2 m}}_{2 m}+
$$

ScIENTIFIC CロMPபTINE LABロRATロRY

Effective actions
Diagonalization Application to BECs Concluding remarks

## Diagrammatic form of effective actions（2）

－Diagrammatic form of recursive relations
－Solutions to level $p=3$

A．Balaž：Properties of Quantum Systems via Num．Diagonalization of the Evolution Operator

## Space-discretized Hamiltonian (1)

- Coordinate representation of the time-independent Schrödinger's equation

$$
\int \mathrm{d} y\langle x| \hat{H}|y\rangle\langle y \mid \psi\rangle=E\langle x \mid \psi\rangle
$$

- Numerical implementation of the exact diagonalization: continuous coordinates $x$ replaced by a discrete space grid $x_{n}=n \Delta$
- To represent this on a computer, we still have to restrict the integers $n$ to a finite range, which is equivalent to introducing a space cutoff $L$, or putting the system in a infinitely high potential box
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Space-discretized Hamiltonian (2)

- For example, the rectangular quadrature rule leads to the following space-discretized Schrödinger equation

$$
\sum_{m=-N}^{N-1} H_{n m}\langle m \Delta \mid \psi\rangle=E(\Delta, L)\langle n \Delta \mid \psi\rangle
$$

where $H_{n m}=\Delta \cdot\langle n \Delta| \hat{H}|m \Delta\rangle, N=[L / \Delta]$

- As a result, we have obtained a $2 N \times 2 N$ matrix that represents the Hamiltonian of the system
- The eigenvalues of this matrix depend on the two parameters introduced in the above discretization process: cutoff $L$ and discretization step $\Delta$
- Continuous physical quantities are recovered in the limit $L \rightarrow \infty$ and $\Delta \rightarrow 0$
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Space-discretized Hamiltonian (3)

- The two approximations $(\Delta, L)$ involved in the discretization procedure are common steps in solving eigenproblems of Hamiltonians
- The system is effectively surrounded by an infinitely high wall, and as the cutoff $L$ tends to infinity, we approach the exact energy levels always from above, which is a typical variational behavior
- The effects of the discretization step $\Delta$ are much more complex, and follow from the fact that the kinetic energy operator cannot be exactly represented on finite real-space grids

## Space-discretized Hamiltonian (4)

- A typical naive discretization of the kinetic energy operator (corresponding to a tight-binding model if $V=0$ )

$$
H_{n m}= \begin{cases}1 / \Delta^{2}+V(n \Delta) & \text { if } n=m \\ -1 /\left(2 \Delta^{2}\right) & \text { if }|n-m|=1 \\ 0 & \text { otherwise }\end{cases}
$$

This leads to numerical results for eigenvalues which converge with $\Delta^{2}$

- The errors associated with this approach have non-variational behavior, i.e. the obtained results are not always upper bounds of the exact energy levels
- The state-of-the-art in this approach is a set of systematically improved prescriptions for discretization of the kinetic energy operator, which speeds up convergence to the continuum limit to higher powers of $\Delta^{2}$
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Space-discretized evolution operator

- Here we instead use the approach of diagonalization of the space-discretized evolution operator, introduced first by Sethia et al. [J. Chem. Phys. 93 (1990) 7268]

$$
\sum_{m=-N}^{N-1} A_{n m}(t)\langle m \Delta \mid \psi\rangle=e^{-t E(\Delta, L, t)}\langle n \Delta \mid \psi\rangle
$$

where $A_{n m}(t)=\Delta \cdot A(n \Delta, m \Delta ; t)=\Delta \cdot\langle n \Delta| e^{-t \hat{H}}|m \Delta\rangle$

- In this approach the time of evolution $t$ plays the role of an auxiliary parameter which is not related to the discretization, but numerically calculated eigenvalues and eigenstates will necessarily depend on it
- We also carefully study the errors associated with the discretization and numerical diagonalization
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Errors due to the spacing $\Delta$ (1)

- The free-particle transition amplitude satisfies $\int \mathrm{d} x A(x, y ; t)=1$, which gives conservation of probability
- In the space-discretized analogue of this model the transition amplitude is $A_{n m}(t)=\Delta A(n \Delta, m \Delta ; t)$
- Using the Poisson summation formula we find that the space discretized free-particle amplitude satisfies

$$
\sum_{n \in \mathbb{Z}} A_{n m}(t)=\sum_{n \in \mathbb{Z}} e^{-\frac{2 \pi^{2}}{\Delta^{2}} n^{2} t} \approx 1+2 \exp \left(-\frac{2 \pi^{2}}{\Delta^{2}} t\right)
$$

- Conservation of probability is thus obtained only in the continuum limit $\Delta \rightarrow 0$

## Errors due to the spacing $\Delta$ (2)

- Note that the effect of discretization is non-perturbative in discretization step $\Delta$, i.e. it is smaller than any power of $\Delta$
- The effect of discretization is also universal - it holds for all models, since the free particle transition amplitude is the dominant term in the short time expansion of the transition amplitude of a general theory
- This leads to discretization errors for energy eigenvalues

$$
E_{k}(\Delta, L, t)-E_{k} \sim-\frac{1}{t} \exp \left(-\frac{2 \pi^{2}}{\Delta^{2}} t\right)
$$

## Errors due to the spacing $\Delta(7)$

$\left|E_{0}(\Delta, L, t)-E_{0}\right|$ for an anharmonic oscillator as a function of $\Delta$ for different values of time of evolution $t$ ，with $L=6, \omega=1$ ， $M=1, g / 24=2$ ．

A．Balaž：Properties of Quantum Systems via Num．Diagonalization of the Evolution Operator

## Errors due to the space-cutoff $L$ (1)

- The effects of space cutoffs are known for continuous-space theories. The shift in energy level $E_{k}(L)-E_{k}$ is found to be positive

$$
E_{k}(L)-E_{k}=C_{k}(a)\left(\int_{a}^{L} \frac{\mathrm{~d} x}{\left|\psi_{k}(x)\right|^{2}}\right)^{-1}
$$

where $a$ is larger than and well away from the largest zero of $\psi_{k}(x)$, but smaller than and well away from the space cutoff $L$

- The constant $C_{k}(a)$ depends on the normalization of eigenfunction and the choice of parameter $a$. For the ground state we can always choose $a=0$, so that

$$
C_{0}(0)=\left(\int_{-L}^{L} \mathrm{~d} x\left|\psi_{0}(x)\right|^{2}\right)^{-1}
$$

A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Errors due to the space-cutoff $L$ (2)

- When we use diagonalization of the discretized amplitudes, the errors in energy level will necessarily also depend on the parameter $t$ and other discretization parameters
- A simple estimate of ground energy errors follows from the spectral decomposition of diagonal amplitudes
- For large $t$ we have $A(x, x ; t) \approx\left|\psi_{0}(x)\right|^{2} e^{-E_{0} t}$. Integrating this we find an approximate result for $E_{0}$ for a system with cutoff $L$

$$
E_{0}(L, t) \approx-\frac{1}{t} \ln \int_{-L}^{L} \mathrm{~d} x A(x, x ; t)
$$

In the $L \rightarrow \infty$ limit we recover the exact ground energy, so that a simple estimate of finite size effects on $E_{0}$ is given by

$$
E_{0}(L, t)-E_{0} \approx \frac{1}{t} \int_{|x|>L} \mathrm{~d} x\left|\psi_{0}(x)\right|^{2}
$$

A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Errors due to the space-cutoff $L$ (3)

$E_{k}(\Delta, L, t)-E_{k}$ for a harmonic oscillator as a function of space cutoff $L$ for different values of time of evolution $t$, with $\Delta=0.1$, $\omega=1, M=1$.
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Evolution-time errors (1)

- The precise calculation of transition amplitudes is essential for applications of this method
- In original and subsequent papers by Sethia et al. all calculations are based on the naive approximation for amplitudes

$$
A^{(1)}(x, y ; t) \approx \frac{1}{(2 \pi t)^{d / 2}} e^{-\frac{(x-y)^{2}}{2 t}-t V\left(\frac{x+y}{2}\right)}
$$

correct only to order $O(t)$.

- If one uses the naive approximation for transition amplitudes, time $t$ must be very short for errors to be small enough
- Such errors are usually much larger than errors due to discretization, which significantly limits the applicability
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Evolution-time errors (2)

- We will use the effective action approach, which gives closed-form analytic expressions $A^{(p)}(x, y ; t)$ for short-time transition amplitudes, converging much faster

$$
A^{(p)}(x, y ; t)=A(x, y ; t)+O\left(t^{p}\right)
$$

- If $p$ is high enough, it is sufficient that the time of evolution is less than the radius of convergence of the above series $\left(t<\tau_{c} \sim 1\right)$ and errors in calculated values of transition amplitudes will be negligible

## Ideal Bose gases（1）

－Good approximation for weakly－interacting dilute gases
－Bose－Einstein condensates usually realized in harmonic magneto－optical traps
－Fast－rotating Bose－Einstein condensates extensively studied
－one of the hallmarks of a superfluid is its response to rotation
－Paris group（J．Dalibard）has recently realized critically rotating BEC of $3 \cdot 10^{5}$ atoms of ${ }^{87} \mathrm{Rb}$ in an axially symmetric trap－we model this experiment
－The small quartic anharmonicity in $x-y$ plane was used to keep the condensate trapped even at the critical rotation frequency［PRL 92， 050403 （2004）］

## Ideal Bose gases（2）

－We apply the developed discretized effective approach to the study of properties of such（fast－rotating）
Bose－Einstein condensates
－We calculate large number of energy eigenvalues and eigenvectors of one－particle states
－We numerically study global properties of the condensate
－$T_{c}$ as a function of rotation frequency $\Omega$
－ground state occupancy $N_{0} / N$ as a function of temperature
－We calculate density profile of the condensate and time－of－flight absorption graphs
－$V_{B E C}=\frac{M}{2}\left(\omega_{\perp}^{2}-\Omega^{2}\right) r_{\perp}^{2}+\frac{M}{2} \omega_{z}^{2} z^{2}+\frac{k}{4} r_{\perp}^{4}, \omega_{\perp}=2 \pi \times 64.8$ $\mathrm{Hz}, \omega_{z}=2 \pi \times 11.0 \mathrm{~Hz}, k=2.6 \times 10^{-11} \mathrm{Jm}^{-4}$

## Calculation of global properties（1）

－Within the grand－canonical ensemble，the partition function of the ideal Bose gas is

$$
\mathcal{Z}=\sum_{\nu} e^{-\beta\left(E_{\nu}-\mu N_{\nu}\right)}=\prod_{k} \frac{1}{1-e^{-\beta\left(E_{k}-\mu\right)}}
$$

The free energy is given by

$$
\mathcal{F}=-\frac{1}{\beta} \ln \mathcal{Z}=\frac{1}{\beta} \sum_{k} \ln \left(1-e^{-\beta\left(E_{k}-\mu\right)}\right)=-\frac{1}{\beta} \sum_{m=1}^{\infty} \frac{e^{m \beta \mu}}{m} \mathcal{Z}_{1}(m \beta)
$$

where $\mathcal{Z}_{1}(m \beta)$ is a single－particle partition function
－The number of particles is given as

$$
N=-\frac{\partial \mathcal{F}}{\partial \mu}=\sum_{m=1}^{\infty}\left(e^{m \beta \mu} \mathcal{Z}_{1}(m \beta)-1\right)
$$

A．Balaž：Properties of Quantum Systems via Num．Diagonalization of the Evolution Operator

## Calculation of global properties（2）

－The usual approach to BEC is to treat the ground state separately，and fix $\mu$ below the condensation temperature $\mu=E_{0}$
－Below the condensation temperature we have

$$
N=N_{0}+\sum_{m=1}^{\infty}\left(e^{m \beta E_{0}} \mathcal{Z}_{1}(m \beta)-1\right)
$$

－The condensation temperature $T_{c}$ is thus defined by the condition：

$$
N_{0}=N-\sum_{m=1}^{\infty}\left(e^{m \beta_{c} E_{0}} \mathcal{Z}_{1}\left(m \beta_{c}\right)-1\right)=0
$$

SCIENTIFIC CロMPபTINE LABロRATロRY

## Calculation of the condensation temperature（1）

Partial sums $\sum_{m=1}^{M}\left(e^{m \beta E_{0}} \mathcal{Z}_{1}(m \beta)-1\right)$ as a function of $M$ for critical rotation，obtained with $p=18$ effective action．

A．Balaž：Properties of Quantum Systems via Num．Diagonalization of the Evolution Operator

## Calculation of the condensation temperature (2)

Number of particles as a function of $T_{c}[\mathrm{nK}]$ for different rotation frequencies, obtained with $p=18$ effective action.

ScIENTIFIC CロMPபTINE LABロRATロRY

## Calculation of the ground－state occupancy

Ground－state occupancy $N_{0} / N$ as a function of $T / T_{c}^{0}$ for different rotation frequencies，obtained with $p=18$ effective action $\left(T_{c}^{0}=110 \mathrm{nK}\right.$ used as a typical scale in all cases）．

A．Balaž：Properties of Quantum Systems via Num．Diagonalization of the Evolution Operator

## Details on the calculation of global properties

- $E_{n}$ can be obtained by the direct diagonalization of the space-discretized propagator, and single-particle partition functions $\mathcal{Z}_{1}(m \beta)$ can be the calculated as

$$
\mathcal{Z}_{1}(m \beta)=\sum_{n} e^{-m \beta E_{n}}
$$

- This is suitable for low temperatures, when higher energy levels (not accessible in the diagonalziation) are negligibe
- For mid-range temperatures, $\mathcal{Z}_{1}$ can be numerically calculated as a sum of diagonal amplitudes, and then $E_{0}$ may be extracted from the free energy

## Density profiles of Bose-Einstein condensates (1)

- Density profile is given in terms of the two-point propagator $\rho\left(\vec{r}_{1}, \vec{r}_{2}\right)=\left\langle\hat{\Psi}^{\dagger}\left(\vec{r}_{1}\right) \hat{\Psi}\left(\vec{r}_{2}\right)\right\rangle$ as a diagonal element, $n(\vec{r})=\rho(\vec{r}, \vec{r})$
- For the ideal Bose gas, the density profile can be written as

$$
n(\vec{r})=N_{0}\left|\psi_{0}(\vec{r})\right|^{2}+\sum_{n \geq 1} N_{n}\left|\psi_{n}(\vec{r})\right|^{2}
$$

where the second term represents thermal density profile

- Vectors $\psi_{n}$ represent single-particle eigenstates, while occupancies $N_{n}$ are given by the Bose-Einstein distribution for $n \geq 1$,

$$
N_{n}=\frac{1}{e^{\beta\left(E_{n}-E_{0}\right)}-1}
$$

A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Density profiles of Bose－Einstein condensates（2）

－Using the cumulant expansion of occupancies and spectral decomposition of amplitudes，the density profile can be also written as

$$
n(\vec{r})=N_{0}\left|\psi_{0}(\vec{r})\right|^{2}+\sum_{m \geq 1}\left[e^{m \beta E_{0}} A(\vec{r}, 0 ; \vec{r}, m \beta \hbar)-\left|\psi_{0}(\vec{r})\right|^{2}\right]
$$

where $A(\vec{r}, 0 ; \vec{r}, m \beta \hbar)$ represents the（imaginary－time） amplitude for one－particle transition from the position $\vec{r}$ in $t=0$ to the position $\vec{r}$ in $t=m \beta \hbar$
－Both definitions are mathematically equivalent
－The first one is more suitable for low temperatures，while the second one is suitable for mid－range temperatures

## Density profiles of Bose-Einstein condensates (3)

$$
\mathrm{t}=0 \mathrm{~ms}
$$

Density profile in $x-y$ plane for the condensate at under-critical rotation $\Omega / \omega_{\perp}=0.9, T=10 \mathrm{nK}<T_{c}=76.8 \mathrm{nK}$. The linear size of the profile is $54 \mu \mathrm{~m}$.
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Density profiles of Bose-Einstein condensates (4)

$t=0 \mathrm{~ms}$

Density profile in $x-y$ plane for the condensate at critical rotation $\Omega / \omega_{\perp}=1, T=10 \mathrm{nK}<T_{c}=63.3 \mathrm{nK}$. The linear size of the profile is $54 \mu \mathrm{~m}$.
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Density profiles of Bose-Einstein condensates (5)

$t=0 \mathrm{~ms}$

Density profile in $x-y$ plane for the condensate at over-critical rotation $\Omega / \omega_{\perp}=1.05, T=10 \mathrm{nK}<T_{c}=55.3 \mathrm{nK}$. The linear size of the profile is $54 \mu \mathrm{~m}$.
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Density profiles of Bose-Einstein condensates (6)

$t=0 \mathrm{~ms}$

Density profile in $x-y$ plane for the condensate at over-critical rotation $\Omega / \omega_{\perp}=1.2, T=10 \mathrm{nK}<T_{c}=49.1 \mathrm{nK}$. The linear size of the profile is $108 \mu \mathrm{~m}$.
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Time-of-flight graphs for BECs (1)

- In typical BEC experiments, a trapping potential is switched off and gas is allowed to expand freely during a short time of flight $t$ (of the order of 10 ms )
- The absorption picture is then taken, and it maps the density profile to the plane perpendicular to the laser beam
- For the ideal Bose condensate, the density profile after time $t$ is given by

$$
n(\vec{r}, t)=N_{0}\left|\psi_{0}(\vec{r}, t)\right|^{2}+\sum_{n \geq 1} N_{n}\left|\psi_{n}(\vec{r}, t)\right|^{2}
$$

where

$$
\psi_{n}(\vec{r}, t)=\int \frac{\mathrm{d}^{3} \vec{k} \mathrm{~d}^{3} \vec{R}}{(2 \pi)^{3}} e^{-i \omega_{\vec{k}} t+i \vec{k} \cdot \vec{r}-i \vec{k} \cdot \vec{R}} \psi_{n}(\vec{R})
$$

A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Time－of－flight graphs for BECs（2）

－For mid－range temperatures we can use mathematically equivalent definition of the density profile

$$
\begin{aligned}
& n(\vec{r}, t)=N_{0}\left|\psi_{0}(\vec{r}, t)\right|^{2}+\sum_{m \geq 1}\left[e^{m \beta E_{0}} \int \frac{\mathrm{~d}^{3} \vec{k}_{1} \mathrm{~d}^{3} \vec{k}_{2} \mathrm{~d}^{3} \vec{R}_{1} \mathrm{~d}^{3} \vec{R}_{2}}{(2 \pi)^{6}} \times\right. \\
& \left.e^{-i\left(\omega_{\vec{k}_{1}}-\omega_{\vec{k}_{2}}\right) t+i\left(\vec{k}_{1}-\vec{k}_{2}\right) \cdot \vec{r}-i \vec{k}_{1} \cdot \vec{R}_{1}+i \vec{k}_{2} \cdot \vec{R}_{2}} A\left(\vec{R}_{1}, 0 ; \vec{R}_{2}, m \beta \hbar\right)-\left|\psi_{0}(\vec{r}, t)\right|^{2}\right]
\end{aligned}
$$

－In both approaches it is first necessary to calculate $E_{0}$ and $\psi_{0}(\vec{r})$ using direct diagonalization or some other method
－FFT is ideally suitable for numerical calculations of time－of－flight graphs

## Time-of-flight graphs for BECs (3)

Evolution of the $x-y$ density profile with the time-of-flight for the condensate at under-critical rotation $\Omega / \omega_{\perp}=0.9, T=10$ $\mathrm{nK}<T_{c}=76.8 \mathrm{nK}$. The linear size of the profile is $54 \mu \mathrm{~m}$.
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Time－of－flight graphs for BECs（4）

Evolution of the $x-y$ density profile with the time－of－flight for the condensate at critical rotation $\Omega / \omega_{\perp}=1, T=10 \mathrm{nK}$ $<T_{c}=63.3 \mathrm{nK}$ ．The linear size of the profile is $54 \mu \mathrm{~m}$ ．

## Time-of-flight graphs for BECs (5)

Evolution of the $x-y$ density profile with the time-of-flight for the condensate at over-critical rotation $\Omega / \omega_{\perp}=1.05, T=10$ $\mathrm{nK}<T_{c}=55.3 \mathrm{nK}$. The linear size of the profile is $54 \mu \mathrm{~m}$.
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

## Time-of-flight graphs for BECs (6)

Evolution of the $x-y$ density profile with the time-of-flight for the condensate at over-critical rotation $\Omega / \omega_{\perp}=1.2, T=10 \mathrm{nK}$ $<T_{c}=49.1 \mathrm{nK}$. The linear size of the profile is $108 \mu \mathrm{~m}$.
A. Balaž: Properties of Quantum Systems via Num. Diagonalization of the Evolution Operator

ScIENTIFIC CロMPபTINE LABロRATロRY

## Time evolution of the density at the origin

Time evolution［s］of the condensate density at the origin of $x-y$ plane for the condensate at various rotation frequencies $\left(r=\Omega / \omega_{\perp}\right)$ for $T=10 \mathrm{nK}<T_{c}$.

## Conclusions (1)

- We have presented a new method for numerical calculation of path integrals for a general non-relativistic many-body quantum theory
- We have derived discretized effective actions which allow deeper analytical understanding of the path integral formalism
- In the numerical approach, discretized effective actions of level $p$ provide substantial speedup of Monte Carlo algorithm from $1 / N$ to $1 / N^{p}$
- For single-particle one-dimensional theories we have derived discretized actions up to level $p=35$, while for a general non-relativistic many-body theory up to level $p=10$

## Conclusions (2)

- For special cases of potentials we have derived effective actions to higher levels ( $p=140$ for a quartic anharmonic oscillator in $d=1, p=67$ in $d=2, p=37$ for modified Pöschl-Teller potential)
- We have developed MC codes that implement the newly introduced approaches, as well as Mathematica codes for automation of symbolic derivation of discretized effective actions
- The derived results used to study properties of quantum systems by numerical diagonalization of the spacediscretized evolution operator
- Numerical study of properties of (fast-rotating) ideal Bose-Einstein condensates
- Condensation temperature and ground-state occupancy
- Density profiles and time-of-flight graphs

## Further applications

- Properties of interacting Bose-Einstein condensates
- Effective actions for time-dependent potentials
- Gross-Pitaevskii (mean field) equation
- Ground states of low-dimensional quantum systems
- Quantum gases with disorder (Anderson localization)
- Improved estimators for expectations values (heat capacity, magnetization etc.)

## Support

- National research project "Numerical Simulations of Complex Systems in Physics (OI141035)", funded by Serbian Ministry of Science
- Centre of Excellence for Computational Modeling of Complex Systems (CX-CMCS) FP6 grant awarded to SCL, Institute of Physics Belgrade
